                                                           2.351375
                                                                      70
                                                                              1
## 6 2.708050 2.079442
                           6.061457 5.288267 8.375860
                                                           2.302585
                                                                      70
                                                                              1
```

a. Run a new regression on the cars_log dataset, with mpg.log. dependent on all other variables

```
cars_log_regr <-
lm(
    mpg ~
        cylinders +
        displacement +
        horsepower +
        weight +
        acceleration +
        year +
        factor(origin),
        data = cars_log
)
summary(cars_log_regr)</pre>
```

```
##
## Call:
## lm(formula = mpg ~ cylinders + displacement + horsepower + weight +
## acceleration + year + factor(origin), data = cars_log)
```

```

```

i. Which log-transformed factors have a significant effect on log.mpg. at 10% significance?

'horsepower', 'weight', 'acceleration', 'year', 'factor(origin)2', and 'factor(origin)3'.

ii. Do some new factors now have effects on mpg, and why might this be?

'acceleration' and 'horsepower' suddenly became significant in this case, which they weren't in the previous homework.

iii. Which factors still have insignificant or opposite (from correlation) effects on mpg? Why might this be?

Only 'cylinders'. The more cylinders cars have, the higher the gas consumption.

b. Let's take a closer look at weight, because it seems to be a major explanation of mpg

i. Create a regression (call it regr_wt) of mpg on weight from the original cars data set

```
regr_wt <- lm(mpg ~ weight, data = Auto)</pre>
```

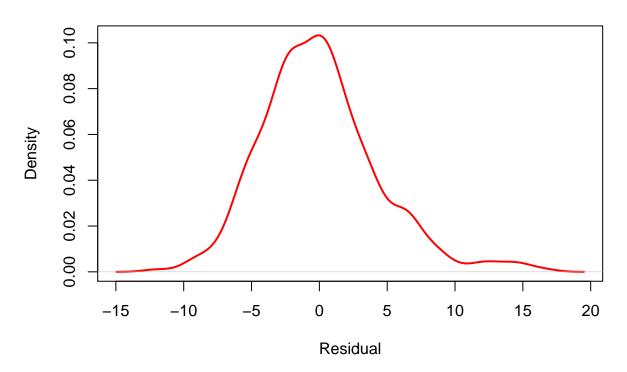

ii. Create a regression (call it regr_wt_log) of log.mpg. on log.weight. from cars_log

```
regr_wt_log <- lm(mpg ~ weight, data = cars_log)</pre>
```

- iii. visualize the residuals of both regression models
- 1. density plots of residuals

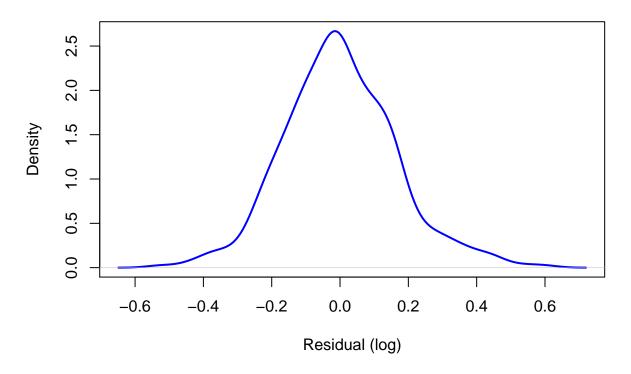

```
plot(
  density(resid(regr_wt)),
  main = "Residual Distribution MPG ~ Weight",
  lwd = 2,
  col = "red",
  xlab = "Residual"
)
```

Residual Distribution MPG ~ Weight

```
plot(
  density(resid(regr_wt_log)),
  main = "Residual Distribution MPG ~ Weight (log)",
  lwd = 2,
  col = "blue",
  xlab = "Residual (log)"
)
```

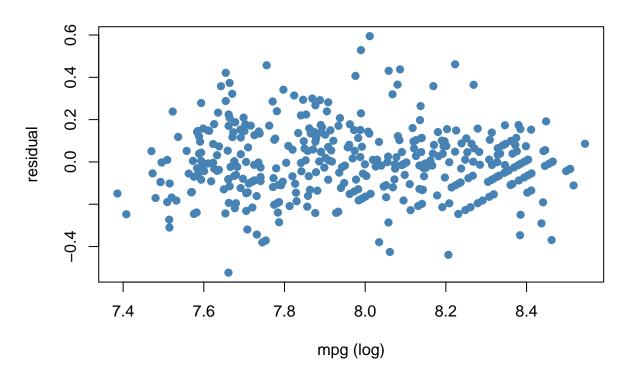

Residual Distribution MPG ~ Weight (log)

2. scatterplot of log.weight. vs. residuals

```
plot(
   cars_log$weight,
   regr_wt_log$residuals,
   col = "steelblue",
   pch = 19,
   xlab = "mpg (log)",
   ylab = "residual",
   main = "Standardized cars' residual"
)
```

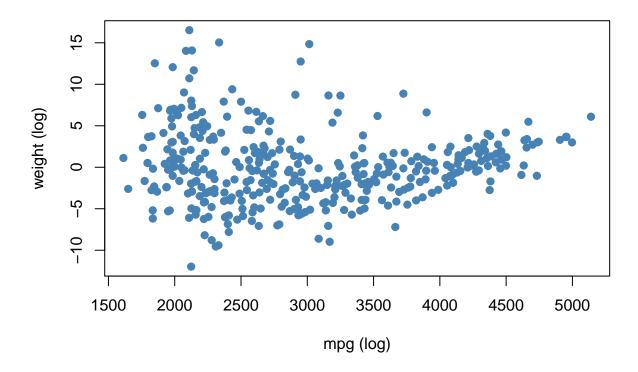

Standardized cars' residual

iv. Which regression produces better residuals for the assumptions of regression?

```
plot(
   Auto$weight,
   regr_wt$residuals,
   col = "steelblue",
   pch = 19,
   xlab = "mpg (log)",
   ylab = "weight (log)",
   main = "Non-standardized cars' residual"
)
```

Non-standardized cars' residual

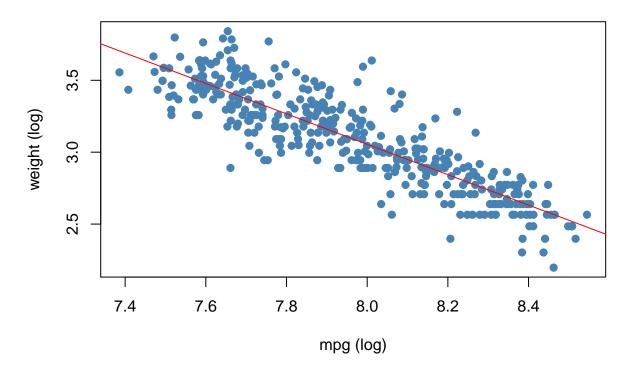

Looking at this graph and the previous graph (the standardized one), we can tell that most data points are centralized in the middle. Thus, the standardized one produces better residuals.

v. How would you interpret the slope of log.weight. vs log.mpg. in simple words?

```
plot(
   cars_log$weight,
   cars_log$mpg,
   col = "steelblue",
   pch = 19,
   xlab = "mpg (log)",
   ylab = "weight (log)",
   main = "Linear model of weight against mpg"
)
abline(a = regr_wt_log$coefficients["(Intercept)"], b = regr_wt_log$coefficients["weight"], col = "red"
```

Linear model of weight against mpg

Clearly, the lighter the cars, the further the distance can be covered per gallon.

```
lm(cars_log$mpg ~ cars_log$weight)
```

```
##
## Call:
## lm(formula = cars_log$mpg ~ cars_log$weight)
##
## Coefficients:
## (Intercept) cars_log$weight
## 11.515 -1.058
```

The summary above also means that 1

- c. Let's examine the 95% confidence interval of the slope of log.weight. vs. log.mpg.
 - i. Create a bootstrapped confidence interval

```
boot_intercept <- function(dataset) {
    # get random data points' indexes
    indexes <- sample(1:nrow(dataset), replace = TRUE)

slopes <- lm(mpg ~ weight, data = dataset[indexes,])</pre>
```

```
abline(slopes, lwd = 1, col="grey")
  return(slopes$coefficients)
}
```

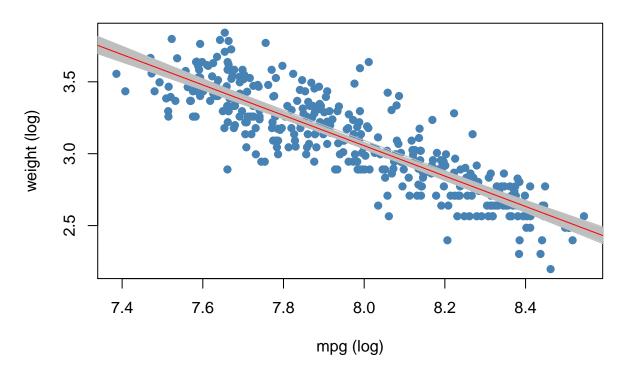

plot(

cars_log\$weight,
cars_log\$mpg,

```
col = "steelblue",
pch = 19,
xlab = "mpg (log)",
ylab = "weight (log)",
main = "95% CI of Intercept Value of MPG ~ Weight"
)

regression_coeffs <- replicate(500, boot_intercept(cars_log))
abline(a = mean(regression_coeffs["(Intercept)",]), b = mean(regression_coeffs["weight",]), col = "red"</pre>
```

95% CI of Intercept Value of MPG ~ Weight

ii. Verify your results with a confidence interval using traditional statistics

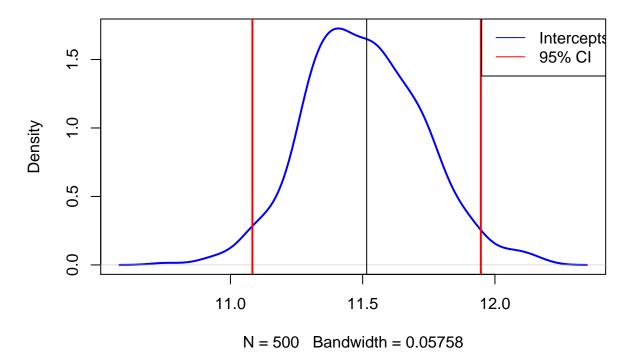

```
plot(
  density(regression_coeffs["(Intercept)",]),
  lwd = 2,
  col="blue",
  main = "Intercept Distribution and its 95% CI"
```

```
abline(
    v = lm(formula = mpg ~ weight, data = cars_log)$coefficients['(Intercept)']
)

abline(
    v = quantile(
        regression_coeffs["(Intercept)",],
        probs = c(0.025, 0.975)
    ),
    col = "red",
    lwd = 2
)

legend(
    11.95,
    1.8,
    c("Intercepts", "95% CI"),
    col = c('blue', 'red'),
    luty = c("solid", "solid")
)
```

Intercept Distribution and its 95% CI

\textcolor{red} { We can see that the regression intercept from $lm(formula = mpg \sim weight, data = cars_log)$ falls in the 95% CI. }

Question 2

```
regr_log <-
lm(
    mpg ~
        cylinders +
        displacement +
        horsepower +
        weight +
        acceleration +
        year +
        factor(origin),
    data = cars_log
)</pre>
```

a. Using regression and R2, compute the VIF of log.weight. using the approach shown in class

[1] 17.57512

displacement 29.625732 1

12.132057 1

horsepower

The result above means that 'weight' shares more than half of its variance with other independent variables.

- b. Let's try a procedure called Stepwise VIF Selection to remove highly collinear predictors.
 - i. Use vif(regr_log) to compute VIF of the all the independent variables

```
library(car)

## Loading required package: carData

regr_log_vif <- vif(regr_log)
regr_log_vif

## GVIF Df GVIF^(1/(2*Df))
## cylinders 10.456738 1 3.233688</pre>
```

5.442952

3.483110

```
## weight 17.575117 1 4.192269
## acceleration 3.570357 1 1.889539
## year 1.303738 1 1.141814
## factor(origin) 2.656795 2 1.276702
```

ii. Eliminate from your model the single independent variable with the largest VIF score that is also greater than 5

```
regr_log <-
lm(
    mpg ~
        cylinders +
        horsepower +
        weight +
        acceleration +
        year +
        factor(origin),
        data = cars_log
)
regr_log_vif <- vif(regr_log)
regr_log_vif</pre>
```

```
GVIF Df GVIF^(1/(2*Df))
##
## cylinders
                  5.433107 1
                                     2.330903
## horsepower
                 12.114475 1

c. Using stepwise VIF selection, have we lost any variables that were previously significant?

- d. From only the formula for VIF, try deducing/deriving the following:
 - i. If an independent variable has no correlation with other independent variables, what would its VIF score be?
 - ii. Given a regression with only two independent variables (X1 and X2), how correlated would X1 and X2 have to be, to get VIF scores of 5 or higher? To get VIF scores of 10 or higher?

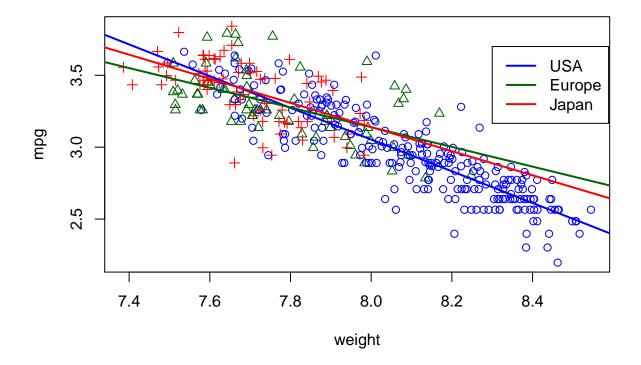

Question 3

```
origin_colors = c("blue", "darkgreen", "red")
with(cars_log, plot(weight, mpg, pch=origin, col=origin_colors[origin]))
legend(
   8.3,
   3.7,
   c("USA", "Europe", "Japan"),
   col = c("blue", "darkgreen", "red"),
   pch = c(1,2,3)
)
```

a. Let's add three separate regression lines on the scatterplot, one for each of the origins:

```
origin_colors = c("blue", "darkgreen", "red")
with(cars_log, plot(weight, mpg, pch=origin, col=origin_colors[origin]))
abline(lm(mpg~weight, data=cars_log[cars_log$origin == 1,]), col=origin_colors[1], lwd=2)
abline(lm(mpg~weight, data=cars_log[cars_log$origin == 2,]), col=origin_colors[2], lwd=2)
abline(lm(mpg~weight, data=cars_log[cars_log$origin == 3,]), col=origin_colors[3], lwd=2)
legend(
    8.3,
    3.7,
    c("USA", "Europe", "Japan"),
    col = c("blue", "darkgreen", "red"),
    lty = c(1,1,1),
    lwd = c(2,2,2)
)
```

b. Do cars from different origins appear to have different weight vs. mpg relationships?

It doesn't seem like it. Cars from those countries show the same trend where the ligher the cars, the further the distance the cars can cover per gallon.
